Gardening in the Global Greenhouse

Prof. Roy Thompson, FRSE
GeoSciences, UoE

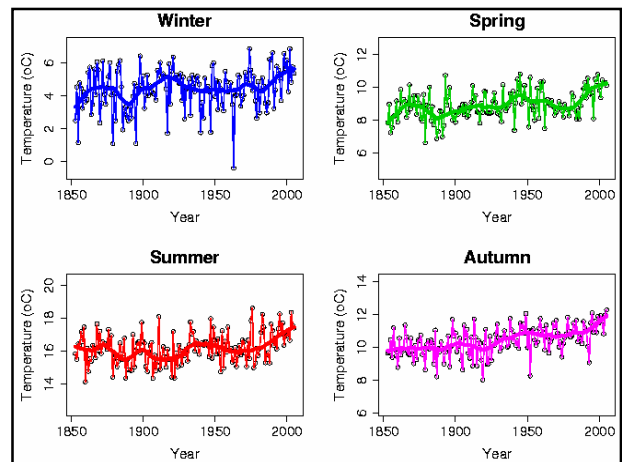

Topics

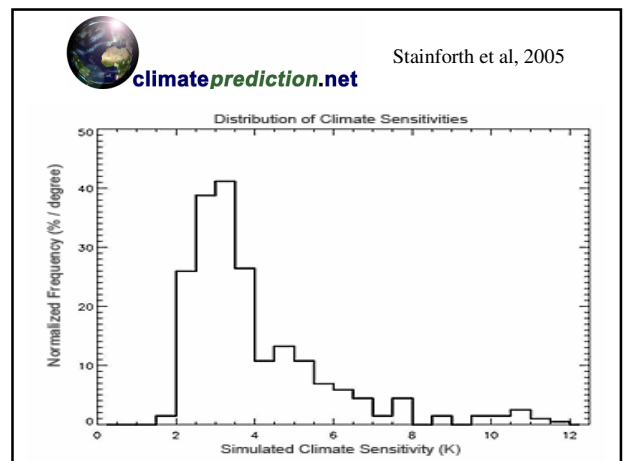

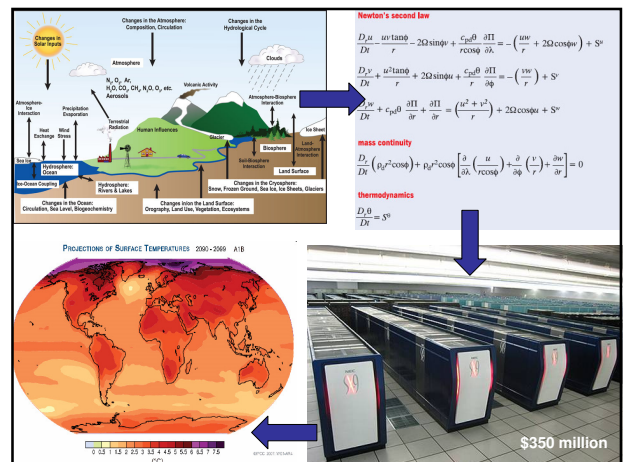

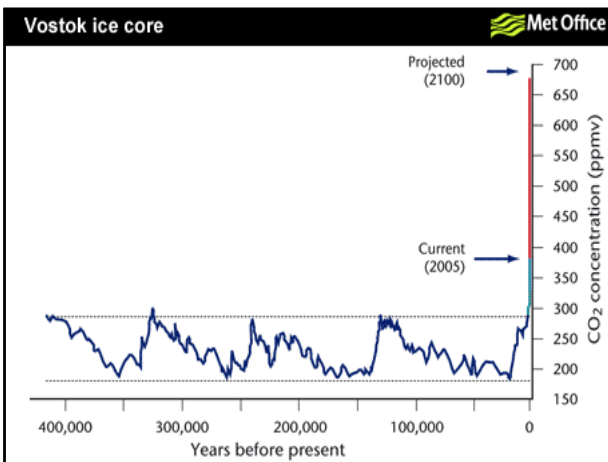

PART I

1. The Scottish climate.
2. The physical process of climate change.
3. Likely climate changes – the range and uncertainties of future greenhouse scenarios.
4. Risks to Scottish gardens and vegetation.

PART II

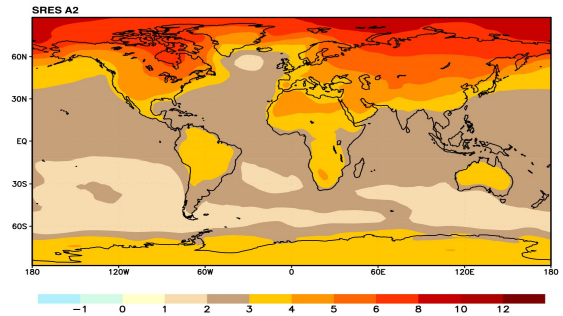

1. Phenology (monitoring flowering and fruiting).

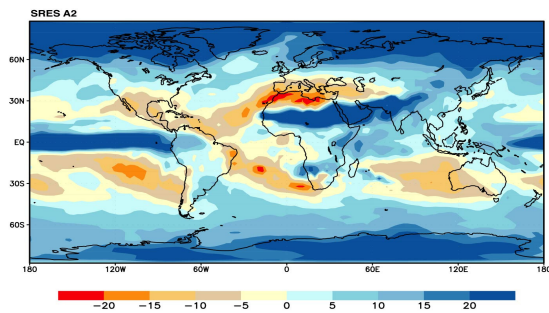

Land areas are projected to warm more than the oceans with the greatest warming at high latitudes

Annual mean temperature change, 2071 to 2100 relative to 1990: global average in 2085 = 3.1°C

Some areas are projected to become wetter, others drier with an overall increase in precipitation

Annual mean precipitation change: 2090 relative to 1990

Summary

1. Climate change is being driven by humans burning fossil fuels, and is accelerating.
2. Temperature increases of 5°C, or more, are very likely this century.
3. The world will become warmer than at any time since the early Eocene Epoch (ca. 50 million years ago).
4. However, climate change in Scotland will be muted compared with that experienced by many other regions.

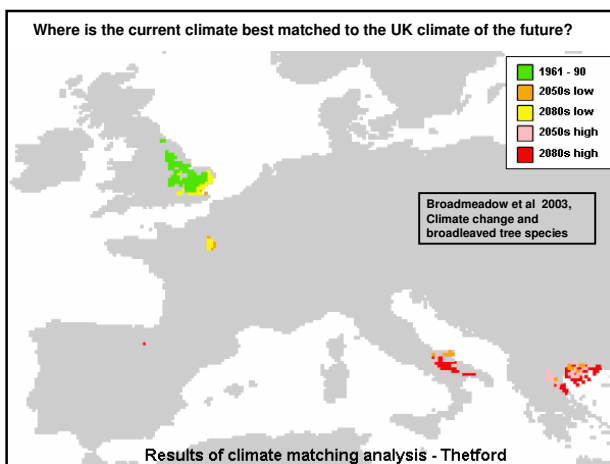

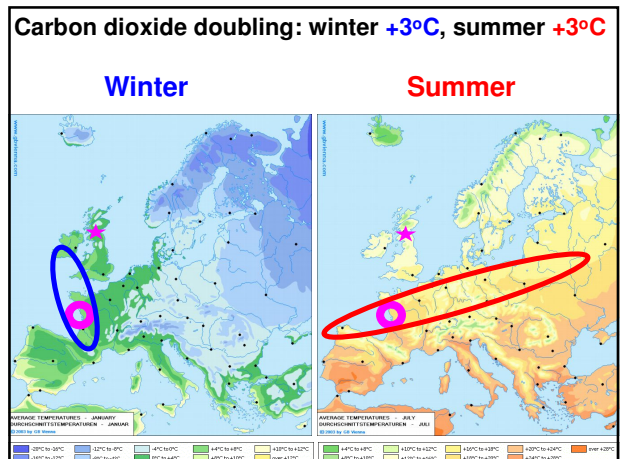

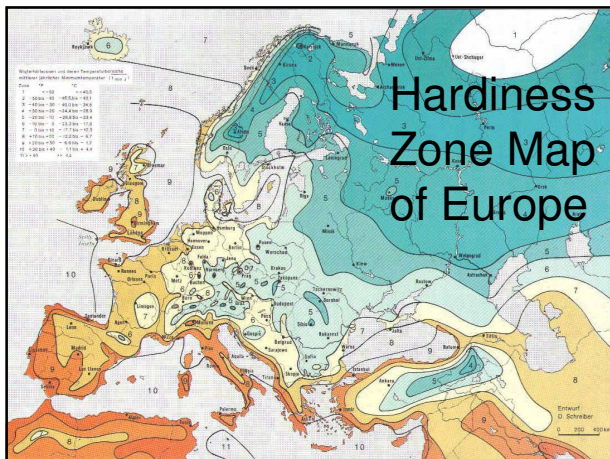

4. Risks to Scottish gardens and vegetation

Projected changes in warmth of Scotland's climate

Accumulated temperature distribution of Scotland's climate: a) baseline climate, 1961–1990; b) projection for 2050; c) projection for 2080.

What is phenology?

- recording nature's signs of the seasons
- the study of the times of recurring natural phenomena especially in relation to climate
- recording when you heard the first cuckoo
- or saw the blackthorn blossom
- your record can then be compared with other records

**Phenology is not
Phrenology nor
Phonology**

Phenological triggers

- Day length
 - Latitude and time of year
 - Not in tropics
- Temperature
 - Year before
 - Month before
 - Day before
- Rainfall

Why is phenology important?

- Timing is everything for survival
- Plant and plant interactions
- Plant and animal species interact
- Complex interactions

Plant animal interactions

You can join in

• Woodland Trust - Nature's calendar survey

- 17 trees & shrubs
- 8 flowers
- 5 grasses
- 21 birds
- 13 insects
- 3 amphibians

- Springwatch
- Autumnwatch

• <http://www.naturescalendar.org.uk/survey>

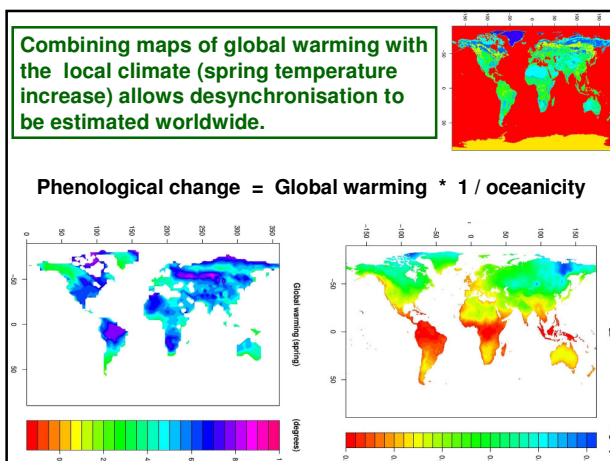

Modelling the response to climate change of the timing of flushing in thirteen temperate trees

Thompson, R. & Clark, R.M.

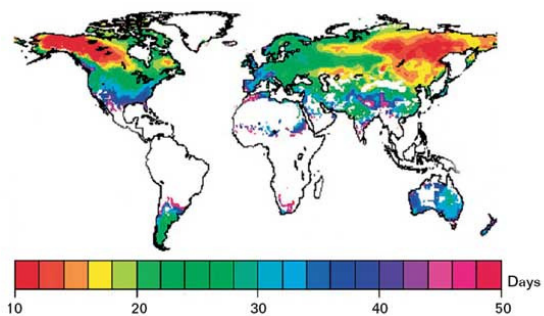

$$\mu_i = \sqrt{\frac{2 \exp(\phi_i)}{m_i}} + \gamma_i + \frac{\kappa}{m_i} \gamma_i$$

where $\phi_i = \ln(\beta + \lambda \gamma_i)$, and λ is the rate of change in thermal requirement, β , associated with changes in the duration of winter chilling; γ is the day on which the spring temperature rise reaches the thermal threshold, α ; κ is α 's rate of change; and m is the rate of increase in spring temperature.

Desynchronisation

Source: School of Geosciences, University of Edinburgh

Colour-coded regions are where plant life will be affected by 2080. Figures reveal the number of days by which plants will flower earlier than expected

A full page spread in the Guardian twisted our global warming message from:

“Massive global desynchronisation of plants and animals leading to disruption of ecosystems”

into

“Women will be happy as more flowers will be available on Saint Valentine's Day”

Summary

1. Phenology is important. Recordings of seasonal occurrences offers real evidence that climate change is happening now and that it is already having a significant effect on our wildlife.
2. Phenological observations are straight forward to make.
3. Contributing observations to the Woodland Trust - Nature's calendar survey - is extremely worthwhile, particularly in the more remote parts of Scotland.
